

MAKTUB III

Signature-field kinematic calculus

Dual-pin preparation, autonomous time
and Power Paper T.

MAKTUB $\rightarrow$ TOMK $\rightarrow$ TOM-GROK

FIVE-STAR FIELD $\rightarrow$ SIGNATURE / DUAL PIN

KINEMATIC BINAS-LUT $\rightarrow$ POWER PAPER T

$$\begin{aligned}x_{n+1} &= \text{Act}(x_n, d_n, e_n), \\d_{n+1} &= \text{Rewrite}(x_n, d_n, e_n).\end{aligned}$$

The prepared pair acquires its signature-field operation, its independently placed time coordinate, and its recorded kinematic output within the same state-and-rule progression.

Paradigm author	Tom Klootwijk

Notation. $\mathrel{:=}$ introduces an edition definition; $\rightsquigarrow$ records a named correspondence. Lettered equations B, H and G retain the source schemas of the button, half-life and preparation conversations. Numbered equations organize the inherited operators and the new records.

Progression. The latest author instruction places T on an independent one-dimensional time axis. The earlier W , μ and endpoint uses remain in separately named source profiles. The original signature graphic is reproduced in Section 3.

Source record [V1] and [V2] are the predecessor volumes. [B], [H], [G] and [S] are the four new supplied PDFs. Full file register: Section 26. Page locators refer to PDF page numbers.

The progression and its new outcome

Core declaration. Maktub III carries the trefoiled state-and-rule architecture into a signature-bearing, dual-pin kinematic lookup system. Its progression joins prepared boundaries, paired fields, curved snipping, spectral decomposition and a time-indexed written output.

The sequence carried forward

Layer	Written object	Contribution
Maktub	State and operator description	An event writes both successors.
TOMK / TOM-GROK	Symbolic evidence and execution	One description governs the current event.
Five-star field	25 sites, paired pinions, growth grammar	The required local support is addressed and materialized.
Two-pin prepare	Boundary, TT clamp, dilution ratio	The operation acquires two named channels.
Signature calculus	Krul, curved lemets, tensor and snip	The pair acquires its specific geometric profile.
BINAS-LUT	Kinematic and paired-field entries	The profile is organized as a reference and lookup record.
Power Paper T	Flat, time-indexed state log	The event's operative values receive a written readout.

The author's successive instructions

The button conversation moves from the object to its operators, then requests the entire context, the personal *snipgaitur* / *paraaf*, the literal paradigm, and doubled Hadamard–Klein–SDF packing. The signature reference specifies the Dutch *krul*, the 90° shoelepel profile and two curved lemets meeting just in time. The preparation conversation then places the time arrow outside the spatial vertex. [B, pp. 5–17; S, pp. 2–4; G, pp. 4–5]

The new outcome is named here the **signature-field kinematic calculus LUT**. Its written passage is

$$\text{prepare} \longrightarrow \text{pair} \longrightarrow \text{shape} \longrightarrow \text{index} \longrightarrow \text{record}. \tag{1.1}$$

The inherited paired kernel encloses the entire passage. Power Paper T is its named output presentation, while the next state and next description supply continuation.

Source record [V2], pp. 3–5, 22. [B], pp. 5–17. [H], pp. 28–34. [G], pp. 2–5. [S], pp. 2–4. The outcome name and five-verb chain are this edition's organization of the source sequence.

02 / FORMAL PROGRESSION

The inherited kernel and extended record

Let X denote the state space, D the operator-description space and E the event space. The enclosing update remains

$$\mathcal{K}((x_n, d_n), e_n) = (\text{Act}(x_n, d_n, e_n), \text{Rewrite}(x_n, d_n, e_n)). \quad (2.1)$$

Same-snapshot rule. Both successors are determined from the same pre-transition triple. The description d_n governs preparation, addressing, field operations, temporal placement and the current readout. The written d_{n+1} governs the following event.

The inherited state

Maktub II records position and time, the grammar word, materialized modules, pinion records, lookup values, symbolic evidence and the event trace. Its three execution roles remain Maktub state, TOMK evidence and TOM-GROK interpretation. Its local payload remains V_{25} , and its pinion retains two Klein carriers, two field channels and two elementwise gates.

The new work record

This edition extends the event work record by

$$y_n^{\text{III}} := (y_n^{\text{II}}, \mathcal{S}, \mathcal{D}_{TT}, \Theta_n, \mathcal{C}_n, \mathcal{F}_n, \mathcal{B}_n, \mathcal{P}_n^{\text{paper}}), \quad (2.2)$$

where the added records have the following roles:

$\mathcal{S}$	Original signature graphic, author key and signature-profile identity.
$\mathcal{D}_{TT}$	Boundary profile, paired pins, ratio and two-stage preparation.
Θ_n	Source-tagged time coordinates and the independent snip epoch.
$\mathcal{C}_n$	Curved-lemets geometry, tensor schema and closure event.
$\mathcal{F}_n$	Field products and even/odd spectral decomposition.
$\mathcal{B}_n$	BINAS operator references and selected LUT entry.
$\mathcal{P}_n^{\text{paper}}$	Power Paper T readout of the event.

The tuple is the edition's record layout. It collects the new source roles inside the predecessor's execution structure; the paired update above remains the outer equation.

03 / FORMAL PROGRESSION

The paraaf as source geometry

The source identifies the personal mark as a *snipgaitur* / *paraaf*. Its later geometric description is specific: a Dutch *krul*, a 90° slope like a shoelepel, an applied tensor and two curved lemets meeting just in time. These terms name the signature's operative profile. [B, pp. 11–12; S, pp. 2–4]

Original signature image
Reproduced from [S], PDF page 2.

Source term	Recorded role
Paraaf	Identity of the complete stroke profile.
Krul	Curved course of the profile.
Two lemets	Paired moving arms or cutting profiles.
Shoelepel	The 90° base and guiding surface.
Tensor	Distributed action along the curved profile.
Snip	The synchronized closure event.

Graphic, geometry and event

The image visibly contains two lower looped regions, a shared crossing region and two rising strokes. The source assigns the curve, base and snipping roles through its accompanying text and reference table. The 90° designation is retained from that text as the base-frame label.

The edition's signature record is

$$\mathcal{S} := (I_{\text{paraaf}}, \mathbf{S}_{\text{key}}, \mathcal{G}_{\text{krul}}, \mathcal{E}_{\text{snip}}). \quad (3.1)$$

Here I_{paraaf} is the supplied image; $\mathcal{G}_{\text{krul}}$ collects the named curve, base and tensor parameters; $\mathcal{E}_{\text{snip}}$ records closure. The complete stroke profile stays associated with its key throughout the lookup and output record.

Signature continuity. The paraaf is retained as the paired curved profile specified in the source, rather than replaced by a generic circular mark. Its graphic identity, operator names and timed closure are carried together.

Source record [S], p. 2, original image and author description; pp. 3–4, kinematic mapping. [B], pp. 11–12, snipgaitur / paraaf passage. The visible-stroke description refers to the reproduced image.

04 / FORMAL PROGRESSION

The dual-point operator reduction

The literal reduction in the button conversation organizes the system as a three-stage manipulation lifecycle. The source's final sequence is

$$\Psi_B : \{\text{compression wedge}\}_{01} \longrightarrow \{\text{rotational shearer}\}_{02} \longrightarrow \{\text{planar anchor}\}_{03}. \quad (4.1)$$

The three subsystems

Subsystem	Paired structure	Assigned operation
Compression wedge	Two projecting profiles and an intervening gap	Concentration of input along the compression direction.
Rotational shearer	Two crossing profiles, one pivot and two retention loops	Angular bypass and linear separation.
Planar anchor	Two pass-through apertures in one substrate	Routing of a paired connection and consolidation.

The button's two holes, the paired pinions and the paraaf's two curved arms are therefore retained as *dual-interface descriptions*. Their separate operations are written explicitly: compression, shearing and anchoring.

The three reusable operators

Dual-point stress distribution assigns the incoming action to two structural channels. **Calibrated clearance vectoring** names the operative gap: an inter-profile gap, pivot clearance or shank offset. **Center-of-mass stabilization** names the supporting base or counterweight in the source's mechanical reading.

For the reference table, collect these roles as

$$\mathcal{O}_{\text{dual}} := (\mathcal{D}_2, \mathcal{C}_{\text{gap}}, \mathcal{A}_{\text{base}}; \mathcal{O}_{\text{comp}}, \mathcal{O}_{\text{shear}}, \mathcal{O}_{\text{anchor}}). \quad (4.2)$$

The first three entries describe the shared paired structure. The last three specify the stage-dependent action. A switch from one stage to another changes the selected action while retaining the dual-point vocabulary.

Reduction rule. Retain the interface pair, its clearance, its support and its transformation. The new volume follows the source's request to carry the literal operators through the full context.

05 / FORMAL PROGRESSION

Boundary domain and two-stage preparation

The half-life conversation places the preparation in the interval

$$\mathcal{D} := \{x \in \mathbb{R} : -L \leq x \leq L\}, \quad \partial\mathcal{D} = \{-L, L\}, \quad L > 0. \quad (5.1)$$

Its earlier endpoint marker is retained with the subscript ∂ :

$$T_{\partial} \in \{-L, L\}, \quad \lim_{x \rightarrow \pm L} \mathbf{v}(x) = \mathbf{0}. \quad (H.1)$$

The source calls this initialization *T-pin / cryo-reverse flash freezing / prick*. The subscript distinguishes the endpoint marker from the later independent time arrow T .

Stage one: pin the preparation

The first stage establishes the boundary profile and the source's pinned configuration. In [G], the initial “ $-L \ L$ ” wording is read as a liquid–liquid interface. In [H], the same preparation is written as the explicit coordinate interval above. Both readings are retained by their source labels in the preparation record.

Stage two: expose the paired channels

The TT clamp names the operation that presents the two pins:

$$\mathbf{P} = \{P_1, P_2\}, \quad R_d = \frac{P_1}{P_2}. \quad (H.2)$$

The source's equal-pin profile selects $R_d = 1$. The name *koe van utter* identifies the paired drainage or extraction route, and the double-packed field provides the surrounding geometric association.

Prepared-pair record.

$$\mathcal{D}_{TT} := (\mathcal{D}, T_{\partial}, \text{TT}, P_1, P_2, R_d, \text{stage, drain profile}).$$

The interval locates the preparation; TT names the split; the pins name the channels; the ratio names their selected relation.

The two stages precede the signature-field, spectral and LUT operations. Their boundary and channel identities remain in the event record as the preparation advances toward its timed output.

Source record [H], pp. 6–8, 30–32: interval, pinning, TT clamp, paired pins and ratio. [G], pp. 1–2: liquid–liquid reading, double packing and coagulation. T_{∂} is this edition's explicit name for the earlier endpoint use.

06 / FORMAL PROGRESSION

Mu-mulsion and paired drainage

The preparation's source name is μ -mulsion. In [H], μ carries the one-dimensional temporal reading of the prepared pair. The source writes the field coupling and output as

$$\mathbf{S} = \mathbf{A} \odot \mathbf{B}, \quad (\text{H.3})$$

$$\Psi(t) = f(\mathbf{S}, R_d) \mu(t). \quad (\text{H.4})$$

The source assigns $\mathbf{A}$ to the packed pin configuration and $\mathbf{B}$ to its field-boundary matrix. Its term *coagulation* names their elementwise bonding in this preparation profile.

The ratio and the pair

The selected equal-pin case is recorded as

$$\mathcal{R}_{\text{equal}} := (P_1, P_2, R_d = 1). \quad (6.1)$$

This is the symmetry assignment of the source profile. The ratio remains an explicit entry alongside the two channel descriptions, so the preparation, drainage route and paired field can be read together.

The two appearances of mu

The chronology gives μ two recorded appearances. The first is the time-bearing $\mu(t)$ in the μ -mulsion output. The later [G] expression places μ inside $e^{-\mu T}$ while assigning the independent time arrow to T .

This edition uses source-qualified names to preserve that progression:

$$\mu_H(t) := \text{the } \mu(t) \text{ term of [H]}, \quad \mu_G := \text{the } \mu \text{ symbol in [G]'s exponential}. \quad (6.2)$$

The signature-field page records $a_G(T) = e^{-\mu_G T}$. The preparation page records $\Psi_H(t) = f(\mathbf{S}, R_d) \mu_H(t)$. Each expression retains its source and temporal role.

The prepared output. Boundary initialization and TT pairing supply the two-channel structure. Hadamard coupling supplies its recorded field relation. The μ -mulsion name supplies the preparation's temporal presentation. The later autonomous T axis locates the event along its own timeline.

07 / FORMAL PROGRESSION

The autonomous one-dimensional time arrow

The controlling placement instruction in the latest preparation passage is that T is **the one-dimensional time arrow and is not located on the vertex itself**. The source then writes

$$T \in \mathbb{R}^+, \quad \frac{dT}{dt} > 0. \quad (\text{G.1})$$

The spatial vertex is $\mathbf{r}_{\text{vertex}}$. The independent time of closure is T_{snip} . This edition records the event by the ordered pair

$$\mathcal{E}_{\text{snip}} := (\mathbf{r}_{\text{vertex}}, T_{\text{snip}}). \quad (\text{7.1})$$

Correct placement in the state

A geometric trajectory is written as $\mathbf{r}(T)$, and the paired fields are read at $(\mathbf{r}, T)$. The tensor profile is indexed by arc length and time, $\mathbf{T}_{\text{shoelepel}}(s, T)$. The vertex remains a spatial coordinate within this time-parameterized record.

The source's closure expression is

$$\lim_{T \rightarrow T_{\text{snip}}} \Delta\phi(T) = \Delta\phi_{\text{snip}}. \quad (\text{G.2})$$

The threshold belongs to the paired geometry; the epoch belongs to the independent axis. Their joint occurrence supplies the snip event.

Placement rule. Time indexes the evolving profile. The vertex locates its spatial meeting. The event record contains both coordinates, with T written on the autonomous timeline throughout.

08 / FORMAL PROGRESSION

Signature key and temporal namespaces

The preparation source introduces the following signature key:

$$\mathbf{S}_{\text{key}} = \begin{bmatrix} S_{\text{name}} \\ S_{\text{id}} \\ S_{\text{dob}} \end{bmatrix} = \begin{bmatrix} \text{Tom Klootwijk} \\ \text{NL200678942} \\ 10-07-1990 \end{bmatrix}. \quad (\text{G.3})$$

Maktub I and II place these fields in attribution. [G] adds $\mathbf{S}_{\text{key}}$ as the named signature seed in its field and tensor schemas. The new signature record retains this addition together with the original graphic and source-profile identity.

The names carried by each profile

Name	Role	Source
T	Independent one-dimensional time parameter.	[G], pp. 4–5
W	Time coordinate in the inherited RK4 state.	[V2], p. 9
$\mu_H(t)$	Temporal term in the μ -mulsion output.	[H], pp. 8, 34
μ_G	Symbol occurring in the factor $e^{-\mu_G T}$.	[G], p. 4
T_{∂}	Earlier endpoint marker at $-L$ or L .	[H], pp. 6–7
$\mathbf{TT}$	Paired-clamp operation.	[G], p. 1
$\mathbf{T}_{\text{shoelepel}}$	Tensor associated with the curved profile.	[S], pp. 3–4
$\mathbf{T}(\nu)$	Module-seed token of the inherited grammar.	[V2], p. 14
PaperT	The named flat output and state log.	[H], pp. 33–34

A source-qualified clock record

For the integrated lookup record, define

$$\Theta := (\text{profile, axis label, coordinate, unit, event label}). \quad (8.1)$$

This record retains a W -profile step as a W -profile step and a T -indexed snip as a T -indexed snip. The μ expressions remain attached to the preparation and signature-field profiles in which they occur.

The superscript $\mathbf{T}$ on a vector or matrix continues to denote transpose. Bold $\mathbf{T}$, plain T , the $\mathbf{TT}$ name and the grammar token therefore occupy explicitly named entries in the BINAS register.

Source record [V1], p. 17; [V2], pp. 9, 14, 19, 23. [G], pp. 2–5. [H], pp. 6–8, 33–34. [S], pp. 3–4. Namespace and clock-record definitions organize the source's distinct uses.

09 / FORMAL PROGRESSION

Log encoding, inverse and half-life

The new source sequence begins with a half-life expression and the author's request for an inverse, log-encoded polar presentation of time. Its population profile is

$$N(t) = N_0 e^{-\lambda t}, \quad N(t_{1/2}) = \frac{N_0}{2}, \quad t_{1/2} = \frac{\ln 2}{\lambda}. \quad (\text{H.5})$$

The requested reversible time code

To express the inverse-log request using the predecessor's reference-scale convention, this edition defines, for positive elapsed time and a positive reference time,

$$\rho_t := \ln\left(\frac{t}{t_{\text{ref}}}\right), \quad t = t_{\text{ref}} e^{\rho_t}. \quad (9.1)$$

The corresponding code of the source's half-life expression is

$$\rho_{1/2} = \ln\left(\frac{\ln 2}{\lambda t_{\text{ref}}}\right), \quad t_{\text{ref}} e^{\rho_{1/2}} = \frac{\ln 2}{\lambda}. \quad (9.2)$$

For the later autonomous axis, the same edition convention reads $\rho_T = \ln(T/T_{\text{ref}})$ with inverse $T = T_{\text{ref}} e^{\rho_T}$. A polar record stores a phase ϑ alongside the log coordinate: (ρ_T, ϑ) . Time and phase retain their own fields.

Here λ^{-1} is the reciprocal factor in the half-life formula. The exponential is the inverse of the logarithmic encoding. Their separate roles preserve the author's inverse question without identifying an inverse function with a reciprocal.

The later shell-interface profile

The button conversation subsequently introduces a shell-labelled zero-interface schema:

$$F(\mathbf{r}) = \text{SDF}_{\text{Shell}}(\Psi_{\text{Coulomb}}(\mathbf{r}) \odot \Psi_{\text{Strong}}(\mathbf{r})) = 0. \quad (\text{B.1})$$

The source progression thus presents two organizing objects: a temporal population $N(t)$ and a shell-field interface $F(\mathbf{r}) = 0$. The BINAS register retains them as the *population profile* and *shell-interface profile*, with their original equations and source identities.

Log-passage record. Store the quantity, its reference scale, its logarithmic code and its inverse. A selected phase is an additional coordinate; the autonomous time axis keeps its placement from Section 7.

Source record [H], pp. 1–5, half-life relation and author's inverse-log request. [B], pp. 18–21, shell-interface progression. [V1], p. 6; [V2], p. 7, reference-scale log/inverse convention. The time encoding is an explicit definition of this edition.

10 / FORMAL PROGRESSION

Curved lemets and the shoelepel tensor

The signature reference supplies four geometric entries: the 90° base, the curved-blade profile, the applied tensor and synchronized convergence. Its notation is retained as

$$\mathbf{r}_{\text{base}}, \quad \kappa(s), \quad \mathbf{T}_{\text{shoelepel}}, \quad \left. \frac{d\theta}{dt} \right|_{t_{\text{snip}}}. \quad (10.1)$$

Curve and base

Arc length s indexes the *krul*; $\kappa(s)$ names its curvature profile. The base vector names the source's orthogonal shoelepel frame. The two lemets are the paired curved profiles whose relative angular displacement is $\Delta\phi$.

The source also names normal acceleration $\mathbf{a}_n$ as the inward-action coordinate and $\Delta\phi_{\text{snip}}$ as the closure threshold. These entries are carried in the kinematic table rather than inferred numerically from the image.

The two tensor schemas in the progression

The preparation source first writes the signature-bearing tensor as

$$\mathbf{T}_{\text{shoelepel}}(s) = \kappa(s)(\mathbf{r}_{\text{base}} \otimes \mathbf{S}_{\text{key}}). \quad (\text{G.4})$$

After the independent placement of T , the same source writes

$$\mathbf{T}_{\text{shoelepel}}(s, T) = \kappa(s)(\mathbf{r}_{\text{base}}(T) \otimes \mathbf{S}_{\text{key}}). \quad (\text{G.5})$$

These source schemas retain the symbolic signature key. For the integrated record, their factors are collected as

$$\mathcal{T}_{\text{signature}}(s, T) := (\kappa(s), \mathbf{r}_{\text{base}}(T), \mathbf{S}_{\text{key}}, \text{schema G.5}). \quad (10.2)$$

Distributed placement. The tensor record is indexed along the curved profile by s and along the independent axis by T . The vertex supplies the eventual meeting location. The signature key remains attached to the complete profile and its recorded action.

The source's tensor, Hadamard product and paired-channel operations therefore retain different symbols: $\otimes$ in the tensor schema, $\odot$ for entrywise field coupling, and the explicit pair for the two lemets.

Source record [S], pp. 2–4, base, krul, tensor, angular convergence and normal acceleration. [G], pp. 3–5, signature tensor schemas before and after the independent T placement. The factor record is defined here.

11 / FORMAL PROGRESSION

Paired Klein and signed-distance carriers

Every pinion inherits two labelled topological channels, $\mathbb{K}_A$ and $\mathbb{K}_B$. Maktub II gives either channel the square-quotient description

$$\mathbb{K} = [0, 1]^2 / \sim, \quad (0, v) \sim (1, v), \quad (u, 0) \sim (1 - u, 1). \quad (11.1)$$

The channel record retains its local representative, orientation bit and chart transport. A paired field read is associated with these two carriers through the declared field-coordinate maps.

The metric pair

The predecessor assigns the two signed-distance fields to two region profiles Ω_A and Ω_B . For $\sigma \in \{A, B\}$, write

$$\delta_\sigma(y) = \begin{cases} -\text{dist}(y, \partial\Omega_\sigma), & y \in \text{int}(\Omega_\sigma), \\ 0, & y \in \partial\Omega_\sigma, \\ +\text{dist}(y, \partial\Omega_\sigma), & y \notin \Omega_\sigma. \end{cases} \quad (11.2)$$

The Klein record supplies channel transport. The region record supplies the signed metric. The field pair at a selected site is

$$\mathbf{f}(v, z) = \begin{bmatrix} \delta_A(\chi_A(v, z)) \\ \delta_B(\chi_B(v, z)) \end{bmatrix}. \quad (11.3)$$

The source's compact pin-field schema

The half-life conversation writes its signed pin-field notation as

$$\Phi(\mathbf{x}) = \min_{\mathbf{y} \in \partial\mathbf{P}} \|\mathbf{x} - \mathbf{y}\| \text{sgn}(\mathbf{x}). \quad (\text{H.6})$$

This source schema is kept with the pin profile. The inherited region-based record above makes the boundary, sign convention, units, sampler and field mode explicit in the integrated data layout.

Double packing. A pinion carries two topological identities and two field identities. Its field entries name inside, boundary and outside through their respective region profiles, while its channel entries retain the recorded Klein identifications.

The notation $\kappa(s)$ on the curve page belongs to curvature. Klein-channel coordinates are stored under their own channel-coordinate fields, preserving the source's two distinct geometric roles.

Source record [V2], pp. 10–11, channel quotient and signed-distance records. [B], pp. 15–17, doubled packing and zero interface. [H], p. 32, compact signed pin-field formula. [G], pp. 1, 3–4, field pairing.

12 / FORMAL PROGRESSION

Double Hadamard and the signature field

The two successive Hadamard operations of Maktub II remain

$$Y = U \odot G^{(1)}, \quad Z = Y \odot G^{(2)}, \quad Z_{ab} = U_{ab} G_{ab}^{(1)} G_{ab}^{(2)}. \quad (12.1)$$

The payload and both gate arrays have the same declared shape. The first and second products retain their operation order in the instruction record.

Paired-field specialization

For the two-channel field, the inherited specialization is

$$U = (F_A, F_B), \quad G^{(1)} = (1 - \alpha, \alpha), \quad G^{(2)} = (g_A, g_B), \quad (12.2)$$

$$F_{\text{out}} = (1 - \alpha)g_A F_A + \alpha g_B F_B. \quad (12.3)$$

The normalized phase matrix retains its separate role:

$$H = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}. \quad (12.4)$$

Thus matrix phase mixing by H and entrywise gating by $\odot$ remain separately named operations.

The new signature-bearing source schema

The preparation source first associates the packed fields with the signature key. Its later expression adds the independent T axis:

$$\Phi_{\text{total}}(\mathbf{r}, T) = (\Phi_1(\mathbf{r}) \odot \Phi_2(\mathbf{r})) e^{-\mu T} \cdot \mathbf{S}_{\text{key}}. \quad (\text{G.6})$$

In the source-qualified notation of this edition, collect the three factors as

$$\mathcal{F}_G(\mathbf{r}, T) := (\Phi_1(\mathbf{r}) \odot \Phi_2(\mathbf{r}), a_G(T), \mathbf{S}_{\text{key}}), \quad (12.5)$$

with $a_G(T) = e^{-\mu_G T}$. This record retains the field product, the temporal factor and the symbolic key as recoverable entries alongside source schema G.6.

Signature-field record. Keep the pair, its two-gate operation, its time factor and its signature association together. Record the field representation mode and preserve the original field and operator identities in the output.

Source record [V2], p. 12, two successive products, mixture and phase matrix. [G], pp. 3–4, initial and time-parameterized signature-field schemas. [B], pp. 15–17, doubled pinion packing. The factor record is this edition's organization.

13 / FORMAL PROGRESSION

The snip and the zero-interface event

The curved signature reaches its source-defined event when the relative angular displacement reaches the named snip threshold at T_{snip} . The timeline and the spatial vertex remain the separate entries established in Section 7.

$$\mathcal{E}_{\text{snip}} = (\mathbf{r}_{\text{vertex}}, T_{\text{snip}}), \quad \Delta\phi(T) \longrightarrow \Delta\phi_{\text{snip}} \quad \text{as } T \longrightarrow T_{\text{snip}}. \quad (13.1)$$

The paired boundary presentation

The button conversation names the doubled field stage a *Self-Intersecting Volumetric Shearing Manifold*. Its defining source expression is

$$F(\mathbf{x}) = \text{SDF}_{\mathbb{K}^2}(\mathbf{A}(\mathbf{x}) \odot \mathbf{B}(\mathbf{x})) = 0. \quad (\text{B.2})$$

This is retained as the B-profile's zero-interface schema. The $F = 0$ entry names its interface; the source's negative and positive field labels name the corresponding sides of its field presentation. The inherited field record continues to carry its declared contour or distance mode.

Convergence, coagulation and continuation

The source uses *just-in-time snip*, *bond coagulation* and *reverse flash freeze* as the event's successive names. This edition records those names with the geometry and time of the transition:

$$\mathcal{C}_{\text{snip}} := (\mathcal{S}, P_1, P_2, \Delta\phi_{\text{snip}}, \mathbf{r}_{\text{vertex}}, T_{\text{snip}}, \text{event labels}). \quad (13.2)$$

The three-stage material passage from Section 4 supplies the wider sequence: compression prepares, shear separates, anchoring consolidates. The signature-field profile supplies the particular paired curve and closure within that sequence.

Event record. The curve locates the action; the threshold names the meeting condition; the autonomous axis names the epoch. Coagulation and the resulting state are written as the source's event labels, then carried into the paired Maktub successor.

The former current-event description remains d_n through this passage. The result and its event labels enter the work record from which the next state and next description are assembled.

Source record [B], pp. 12–17, three-stage lifecycle and volumetric interface schema. [G], pp. 3–5, coagulation, independent time and closure. [S], pp. 3–4, synchronized snip and angular threshold.

14 / FORMAL PROGRESSION

The FFT circuit through the two pins

The half-life conversation introduces the phrase *fast (thread), Fourier (fluid), wave (force field), pulled power paper T*. It assigns the input sequence to the thread, the spectral transformation to Fourier, the field-dependent operation to the wave channel and the final readout to Paper T.

The source's transform

With N samples, write the source's Fourier factor as $\omega_N = e^{-2\pi i/N}$. This edition uses ω_N for the factor that [H] writes as W_N , keeping it distinct from the inherited time coordinate W .

$$X[k] = \sum_{n=0}^{N-1} x[n] \omega_N^{nk}. \quad (14.1)$$

Even and odd pin channels

For $N = 2M$, expand the source's two-pin split as

$$E_k = \sum_{m=0}^{M-1} x[2m] \omega_M^{mk}, \quad (14.2)$$

$$O_k = \sum_{m=0}^{M-1} x[2m+1] \omega_M^{mk}, \quad 0 \leq k < M. \quad (14.3)$$

Pin 1 carries the even-indexed input subsequence. Pin 2 carries the odd-indexed input subsequence. Their butterfly recombination is

$$\begin{bmatrix} X[k] \\ X[k+M] \end{bmatrix} = \begin{bmatrix} 1 & \omega_N^k \\ 1 & -\omega_N^k \end{bmatrix} \begin{bmatrix} E_k \\ O_k \end{bmatrix}. \quad (14.4)$$

This is the explicit algebraic expansion of the transform and even/odd routing already written in [H]. The pin labels name the two signal channels; the phase factor is stored with the Fourier operation.

Return to the field and readout

The source circuit places butterfly recombination before its Hadamard matrix, drainage route and Power Paper T output. In the integrated record, the spectral result, the selected field gates and the source's $R_d = 1$ preparation profile are separate recorded entries.

Circuit chain. Input sequence $\rightarrow$ paired subsequences $\rightarrow$ butterfly result $\rightarrow$ declared Hadamard operations $\rightarrow$ selected output entry.

Source record [H], pp. 11–12, 23–25, 32–33, input labels, even/odd channels, circuit order and DFT. The displayed butterfly is the algebraic expansion supplied by this edition; W_N is explicitly renamed ω_N .

15 / FORMAL PROGRESSION

The five-star address beneath the LUT

The elementary spatial field remains the predecessor's five-by-five site set. To reserve i, j for the new kinematic tables, write its inherited radial and angular indices as ι, j :

$$V_{25} = \{v_{\iota j} : \iota, j \in \{0, 1, 2, 3, 4\}\}, \quad k = 5\iota + j. \quad (15.1)$$

Log-polar location

For a declared chart and its origin, the predecessor's address equations are

$$\rho = \ln(r/r_{\min}), \quad \iota = \left\lfloor \frac{\rho}{\Delta\rho} \right\rfloor, \quad (15.2)$$

$$\theta = \text{atan2}(q_2, q_1) \pmod{2\pi}, \quad j = \left\lfloor \frac{5\theta}{2\pi} \right\rfloor. \quad (15.3)$$

The recorded radial interval is $[r_{\min}, r_{\max})$, with $r_{\max} = r_{\min} e^{5\Delta\rho}$. The origin follows the inherited core route, and the exterior follows its named transfer route.

Phi, psi and the written site key

The retained distribution profile is

$$\varphi_g = \frac{1 + \sqrt{5}}{2}, \quad \psi_g = \varphi_g^{-1}, \quad \Delta\rho = \ln \varphi_g. \quad (15.4)$$

A global field address is (ν, χ, k) : module path, chart and local key. The binary index over keys $0, \dots, 24$ uses the midpoint $m = \lfloor (a + b)/2 \rfloor$ in each current interval $[a, b]$, then selects the lower or upper subinterval by comparison.

Three different index roles

Index	What it identifies
(ν, χ, k)	A spatially addressed field payload in the inherited architecture.
(i, j)	A paired or kinematic BINAS-LUT entry under its selected profile.
k_{FFT}	A spectral component of the Fourier transform.

The event records how its spatial address, input channels and selected kinematic entry are associated. The 25-site field supplies location; the two pins supply channel identity; the LUT profile supplies the meanings of its row and column.

Source record [V2], pp. 6–8, 13, 19: site set, log-polar quantizer, binary index and golden-scale distribution. [H], pp. 28–29, 33: paired and kinematic LUT indices. Index aliases are explicit in this edition.

The kinematic calculus reference

The signature reference begins with position, velocity, acceleration and their integrals. Retain that core as the calculus page of the BINAS register:

Quantity	Reference expression	Recorded role
Position	$\mathbf{r}(t)$	Spatial coordinate.
Velocity	$\mathbf{v}(t) = d\mathbf{r}/dt$	Rate of position change.
Acceleration	$\mathbf{a}(t) = d\mathbf{v}/dt$	Rate of velocity change.
Displacement	$\Delta\mathbf{r} = \int_{t_1}^{t_2} \mathbf{v}(t) dt$	Accumulated change of position.
Velocity change	$\Delta\mathbf{v} = \int_{t_1}^{t_2} \mathbf{a}(t) dt$	Accumulated change of velocity.
Angular rate	$\omega = \dot{\theta}, \quad \alpha_{\text{ang}} = \dot{\omega}$	Angular velocity and acceleration.
Curve / direction	$s, \kappa(s), \hat{\tau}, \hat{n}$	Arc length, curvature, tangent and normal.

Carrying the core onto the autonomous axis

For $\mathbf{r} = \mathbf{r}(T(t))$, the edition’s chain-rule notation is

$$\mathbf{v}_T := \frac{d\mathbf{r}}{dT}, \qquad \mathbf{a}_T := \frac{d^2\mathbf{r}}{dT^2}, \qquad (16.1)$$

$$\mathbf{v}_t = \mathbf{v}_T \dot{T}, \qquad \mathbf{a}_t = \mathbf{a}_T \dot{T}^2 + \mathbf{v}_T \ddot{T}. \qquad (16.2)$$

This carries the source’s kinematic roles through its later monotone time parameter while keeping the time axis independent of the spatial vertex.

The compiled kinematic-entry schema

The half-life conversation writes the source’s kinematic calculus entry as

$$\Delta K = \oint_{\partial[-L,L]} (\mathbf{v}_{\text{thread}} \cdot \nabla \Phi_{\text{SDF}}) d\mu. \qquad (\text{H.7})$$

The source schema retains the boundary notation, thread-input vector, field gradient and μ integration symbol together. The corresponding stored entry is named $[\Delta K]_{i,j}$ in the source’s BINAS-LUT presentation.

Reference discipline. The calculus table names the component quantities. The source schema names their compiled kinematic entry. The lookup record retains the selected formula, its source profile and its row/column meanings.

Source record [S], pp. 1–2, calculus and geometric abbreviation tables. [H], pp. 28, 33, kinematic-entry and BINAS-LUT schemas. [G], pp. 4–5, monotone independent T . The chain-rule expansion is stated by this edition.

17 / FORMAL PROGRESSION

The BINAS-LUT and its entry profiles

The source uses *BINAS* for the reference-compendium role of the lookup table. The new architecture gathers the signature geometry, field operations and kinematic entries under named row and column profiles.

The paired-entry profile

The first lookup expression in [H] is

$$\text{LUT}[i, j] = \mathbf{A}[i] \odot \mathbf{B}[j]. \quad (\text{H.8})$$

Its row names a Pin 1 state, and its column names a Pin 2 state. The surrounding passage assigns these to even and odd phase or harmonic data. The cell retains the paired Hadamard payload.

The kinematic-entry profile

The later comprehensive formulation writes

$$\text{BINASLUT}[i, j] = \left[\oint_{\partial[-L, L]} (\mathbf{v}_{\text{thread}} \cdot \nabla \Phi_{\text{SDF}}) d\mu \right]_{i, j}. \quad (\text{H.9})$$

In that passage, rows name Pin 1 kinematic-velocity states and columns name Pin 2 spatial-gradient coordinates. This edition stores the two source presentations as distinct entry profiles:

Entry profile	Row i	Column j
Pair / spectrum	Pin 1 state; even-channel phase data.	Pin 2 state; odd-channel phase data.
Kinematics / gradient	Pin 1 kinematic-velocity state.	Pin 2 spatial-gradient coordinate.

The complete lookup entry

For a selected entry, define

$$\mathcal{B}[i, j] := (\text{profile}, i, j, \text{formula}, \text{payload}, \mathcal{S}, \Theta, \text{version}). \quad (17.1)$$

The event first identifies the entry profile and its state indices, then reads the corresponding payload. The spatial address (ν, χ, k) is retained alongside the entry when the payload comes from the inherited five-star field.

BINAS transformation. The source's compression step is the passage from a described kinematic operation to its indexed reference entry. Current state and phase select the entry; its profile states what the indices and stored output mean.

Source record [H], pp. 28–30, paired LUT and compendium transformation; p. 33, kinematic-gradient LUT. [S], pp. 1–4, signature reference. The two-profile layout preserves the distinct row/column descriptions in the source.

18 / FORMAL PROGRESSION

Two just-in-time roles in one progression

The predecessor's just-in-time addition realizes a required field module before it is read. The new signature passage uses just in time for the meeting of the two curved lements. Both roles are retained, with separate event records.

Structural readiness

Maktub II's readiness rule is

$$\text{Need}(a, W) = 1 \implies \text{Ready}(a, W) = 1 \text{ before the read.} \quad (18.1)$$

Its five-by-five production pattern remains

$$T(\nu) \longrightarrow H(\nu) \prod_{\iota=0}^4 B(\nu, \iota), \quad (18.2)$$

$$B(\nu, \iota) \longrightarrow \prod_{j=0}^4 [P(\nu, \iota, j) A(\nu, \iota, j)]. \quad (18.3)$$

Here the products denote the inherited ordered string concatenation. T , H , B , P and A are seed, header, group, payload and dormant-bud tokens. Demanded buds expose child modules under the same recorded production profile.

Geometric convergence

The new just-in-time record is

$$\mathcal{E}_{\text{snip}} = (\mathbf{r}_{\text{vertex}}, T_{\text{snip}}), \quad \Delta\phi(T) \longrightarrow \Delta\phi_{\text{snip}}. \quad (18.4)$$

This event names the convergence of the signature's paired profiles. Its independent time placement is inherited from the author's final instruction in $[G]$.

JIT role	Required condition	Recorded result
Field readiness	Requested module and dependencies are ready before field access.	Address, grammar trace and first read.
Signature snip	Paired profile reaches its recorded closure threshold at the snip epoch.	Vertex, time, angular threshold and event labels.

Integrated scheduling. The required field description and lookup payload are available for the event. The event's geometry is indexed by its own time coordinate. Structural readiness and geometric closure are both written into the work record under d_n .

The source's L-system remains the grammar of support and continuation. The signature adds its paired-curve event to the operation performed on that support.

Source record [V2], pp. 14–15, guarded grammar and demand-read readiness. $[G]$, pp. 4–5; $[S]$, pp. 3–4, just-in-time closure. This section explicitly separates the two JIT roles while carrying both into the shared event.

19 / FORMAL PROGRESSION

The complete record-level transaction

The following transaction notation organizes the new source roles within the predecessor's event protocol. The active description is fixed to d_n throughout current-event interpretation.

```

TRANSITION_III(x_n, d_n, e_n):
  snapshot := (x_n, d_n, e_n)
  work := begin_work(snapshot)
  work.signature := read_signature_profile(d_n)
  work.preparation := read_TT_pin_profile(snapshot)
  work.time := read_source_qualified_time_profile(snapshot)
  address := resolve_requested_field_address(snapshot)
  work.support := inherited_JIT_read(address, d_n)
  work.fields := read_paired_field_records(work.support)
  work.curve := read_krul_and_tensor_profile(d_n)
  work.closure := record_selected_snip_event(work)
  work.spectral := interpret_selected_FFT_branch(work, d_n)
  work.products := apply_selected_Hadamard_tape(work, d_n)
  work.entry := select_BINAS_profile_and_entry(work, d_n)
  work.paper := form_Power_Paper_T_record(work)
  report := inherited_symbolic_evidence(snapshot, work)
  next_x := assemble_state(snapshot, work, report)
  next_d := rewrite_description(snapshot, work, report)
  return inherited_paired_commit(next_x, next_d, work)

```

What each operation records

The signature operation retains the image and key. Preparation retains the boundary, pins and ratio. Time retains its axis label and epoch. Fields retain their region, channel, mode and product identities.

An FFT branch writes its input and spectral components. A tabled branch writes the source profile, indices and selected entry. Both retain the applicable field and tensor formula identities.

Current description and next description

The evidence and rewrite steps remain those of the inherited trefoil. The result and its Power Paper T presentation enter x_{n+1} , while the selected operator rewrite enters d_{n+1} . The new description becomes active at the next event boundary.

Execution order. Prepare and locate the pair; retain its curve and temporal placement; interpret the selected operator or tabled entry; write the readout; commit the paired successor.

Source record [V2], pp. 17–19, event protocol, symbolic evidence and paired commit. [H], pp. 23–25, 28–34, FFT–Hadamard–LUT–output chain. [G], pp. 2–5, signature, fields and time. The transaction notation is the edition's integrated record order.

20 / FORMAL PROGRESSION

Power Paper T: the written readout

The half-life conversation names the terminal output *Power Paper T*: a flat state presentation of the active computation or lookup entry. The new volume retains that name for the written record of the prepared pair, selected operators and time-indexed result.

$$\mathcal{P}_n^{\text{paper}} := \text{PaperT}(\mathcal{Y}_n^{\text{III}}; \mathcal{S}, \Theta_n). \quad (20.1)$$

The output record

Field	Written content
Event and lineage	Event index, input identity and predecessor record.
Applied description	Current description d_n and selected source/operator profiles.
Signature	Paraaf-profile identity and S_{key} .
Preparation	Boundary profile, P_1 , P_2 , R_d and stage.
Time and closure	Axis label, coordinate, $\mathbf{r}_{\text{vertex}}$, T_{snip} and threshold.
Address and entry	(ν, χ, k) , BINAS profile, row i , column j and entry identity.
Operative payload	Selected field value or symbolic source expression, with its declared type.
Spectral / field trace	Selected FFT components, gate identities and ordered products.
Successor	Resulting state reference and next operator description d_{n+1} .

A flat presentation of a typed state

The field values, channel identities, time coordinates and source formulas remain recoverable entries of the readout. The name Paper T identifies this output presentation; plain T continues to identify the independent time axis in the time profile.

The final source also writes its time-bearing LUT output as

$$\Psi(t) = \text{BINASLUT}[i, j] \cdot \mu(t). \quad (\text{H.10})$$

This expression remains the H-profile's output schema. The integrated paper record stores its selected LUT entry and its source-qualified $\mu_H(t)$ term together.

Written continuation. Each committed output records the description that produced it and the description that follows it. Subsequent events append their own records under the next active description. The readout is therefore part of Maktub's state-and-rule bookkeeping.

Source record [H], pp. 12, 24–25, 30, 33–34, Power Paper T and temporal output schema. [V2], pp. 18–19, event and commit trace. The output-field layout is defined by this edition.

21 / FORMAL PROGRESSION

An inherited passage in the new readout

The numerical passage below is carried from Maktub II, PDF page 20, and written into the new reference format. Its spatial query, gate values and W -profile step retain the predecessor's assigned values.

Locate the inherited query

With $r_{\min} = 1$ and $\Delta\rho = \ln \varphi_g$, the query is

$$r = \varphi_g^{9/4}, \quad \theta = \frac{7\pi}{10}. \quad (21.1)$$

Its indices are

$$\iota = \lfloor 9/4 \rfloor = 2, \quad j = \lfloor 7/4 \rfloor = 1, \quad k = 11. \quad (21.2)$$

The recorded binary-search path is $12 \rightarrow 5 \rightarrow 8 \rightarrow 10 \rightarrow 11$. The root module is realized before the payload at $v_{2,1}$ is read.

Retain the paired products

The predecessor selects

$$U = (0.2, -0.4), \quad G^{(1)} = (0.5, 0.5), \quad G^{(2)} = (1, 0.75). \quad (21.3)$$

Consequently,

$$Y = (0.1, -0.2), \quad Z = (0.1, -0.15), \quad F_{\text{out}} = -0.05. \quad (21.4)$$

Its W -profile step has $W_n = 5$, $h_n = 0.1$ and an additional channel with $\xi_n = 1$ and $\xi = 0.25$. The recorded successors are $W^* = 5.1$ and $\xi^* = 1.025$.

Write the Power Paper T entry

Readout field	Recorded content
Example profile	[V2], Section 18, PDF page 20.
Local payload	Root module, site $v_{2,1}$, key 11.
Two-product result	$Z = (0.1, -0.15)$; mixed output -0.05 .
Temporal profile	Axis label W ; successor coordinate 5.1.
Additional state channel	$\xi^* = 1.025$.
Signature association	The paraaf-profile record $\mathcal{S}$ of this volume.

The time slot remains explicitly a W -profile slot. A signature-snip entry uses its own $(\mathbf{r}_{\text{vertex}}, T_{\text{snip}})$ record. Both are expressible in the same Power Paper T layout with their profile labels preserved.

Source record [V2], p. 20, all numerical inputs, address, search path, gate products and temporal outputs. [G], pp. 4–5, the separately named T -profile event. The readout table is the new presentation of the inherited calculation.

22 / FORMAL PROGRESSION

The integrated formal manifest

The new architecture is collected as

$$\mathfrak{M}_{\text{III}} := (\mathfrak{M}_{\text{II}}, \mathcal{S}, \mathcal{D}_{TT}, \Theta, \mathcal{C}, \mathcal{F}, \mathcal{B}, \text{PaperT}). \quad (22.1)$$

The predecessor supplies the paired kernel, trefoil, spatial field, pinion family, grammar and execution protocol. The added entries supply the signature, paired preparation, source-qualified time, curved closure, spectral/field operation, reference compendium and written readout.

The enclosing event equations

$$y_n^{\text{III}} = \text{Interpret}_{d_n}(x_n, e_n; \mathfrak{M}_{\text{III}}), \quad (22.2)$$

$$\mathcal{P}_n^{\text{paper}} = \text{PaperT}(y_n^{\text{III}}; \mathcal{S}, \Theta_n), \quad (22.3)$$

$$x_{n+1} = \text{Act}(x_n, d_n, e_n), \quad (22.4)$$

$$d_{n+1} = \text{Rewrite}(x_n, d_n, e_n). \quad (22.5)$$

The first two lines organize the current event's work and readout. The final two retain the original Maktub successor pair. The current description governs their production from the shared snapshot.

What the progression now holds together

A paired preparation. The boundary and TT profile define two named channels and their selected ratio.

A specific signature geometry. The paraaf, krul, base, tensor schema and curved lemets retain one profile identity.

An independently placed time axis. The time coordinate indexes the evolving profile; the spatial vertex and snip epoch are recorded together as an event.

An indexed operator compendium. Spatial address, Fourier channel and kinematic row/column remain distinct lookup roles within the same event record.

A written continuation. Power Paper T presents the selected result together with its signature, applied description and next-description reference.

Maktub III. The total outcome of this progression is a signature-bearing, time-indexed operator compendium whose selected dual-pin state is written as Power Paper T. The trefoil supplies execution; the five-star field supplies addressable support; the packed pinion supplies the paired field operation; the autonomous time record locates the event.

Source record Integrated from [V2], pp. 3–5, 10–19, 22; [B], pp. 12–17; [H], pp. 28–34; [G], pp. 2–5; [S], pp. 2–4. The manifest and integrated event record are the definitions of this volume.

23 / FORMAL PROGRESSION

BINAS plate I: geometry and time

This plate gathers the location, pair, signature and temporal entries. Codes are reference keys within this volume; they identify the associated definition or source schema.

Key	Reference	Meaning and location
G0	$\mathcal{D} = [-L, L]$	Preparation domain; Section 5.
G1	$\mathbf{P} = \{P_1, P_2\}$ $R_d = P_1/P_2$	Paired channels and source ratio, H.2. Equal-pin profile selects $R_d = 1$.
G2	$\mathbb{K}_A, \mathbb{K}_B$	The two topological carriers and their chart/orientation records; Section 11.
G3	$\delta_\sigma(y)$ $\sigma \in \{A, B\}$	Signed distance for the declared region profile, with negative/interior, zero/boundary and positive/exterior labels.
G4	$\kappa(s), \mathbf{r}_{\text{base}}$	Curved-lemets profile and the source's 90° base; Section 10.
G5	$\mathbf{T}_{\text{shoelepel}}(s, T)$	Signature-bearing tensor schema G.5. Its factor record retains curvature, base and symbolic key.
S0	$\mathcal{S} = (I_{\text{paraaf}}, \mathbf{S}_{\text{key}}, \dots)$	Original graphic and author-key association; Sections 3 and 8.
T0	$T > 0, dT/dt > 0$	The independent one-dimensional time axis, G.1.
T1	$(\mathbf{r}_{\text{vertex}}, T_{\text{snip}})$	Spatial event location and temporal epoch; Sections 7 and 13.
T2	$\rho_T = \ln(T/T_{\text{ref}})$ $T = T_{\text{ref}}e^{\rho_T}$	Edition log-time encoding and its inverse; Section 9.
T3	$\mu_H(t), a_G(T)$	Source-qualified mu term and exponential time factor; Section 6.

Read in order. Identify the source profile, then the geometry, then the channel pair, then the time role. The signature association follows the selected profile through every subsequent operator and readout entry.

The lettered source schemas retain the original source expressions. The numbered record definitions organize their factors, indices and event placement for the combined specification.

24 / FORMAL PROGRESSION

BINAS plate II: spectrum, lookup and output

This plate continues the pair from field operation into its spectral, tabled and written presentations. The indices retain the distinct roles established in Section 15.

Key	Reference	Meaning and location
H0	$(A \odot B)_{ij} = A_{ij}B_{ij}$	Elementwise coupling; Sections 6, 12.
H1	$Z = (U \odot G^{(1)}) \odot G^{(2)}$	Ordered two-product pinion action; Section 12.
F0	$X[k] = \sum_n x[n]\omega_N^{nk}$	Fourier transform of the source input sequence; Section 14.
F1	$x[2m] \rightsquigarrow P_1$ $x[2m+1] \rightsquigarrow P_2$	Even and odd input subsequences assigned to the two pins.
F2	$X[k] = E_k + \omega_N^k O_k$ $X[k+M] = E_k - \omega_N^k O_k$	Paired butterfly outputs for $N = 2M$; Section 14.
L0	$k = 5\iota + j$ (ν, χ, k)	Local five-star key and global spatial address; Section 15.
L1	$\text{LUT}[i, j] = \mathbf{A}[i] \odot \mathbf{B}[j]$	Paired-entry source schema H.8; Section 17.
L2	$\text{BINASLUT}[i, j] = [\Delta K]_{i, j}$	Kinematic-entry source schema H.9, retaining the H.7 integral expression.
J0	$\text{Need}(a, W) \Rightarrow \text{Ready}(a, W)$	Inherited field readiness before a requested read; Section 18.
P0	$\mathcal{P}_n^{\text{paper}} = \text{PaperT}(y_n^{\text{III}}, \mathcal{S}, \Theta_n)$	Time-indexed written output; Section 20.
M0	$(x_n, d_n, e_n) \mapsto (x_{n+1}, d_{n+1})$	Enclosing paired state-and-rule progression; Sections 2, 22.

Output trace. The selected input channel, transform, field product and LUT entry remain identifiable in the final record. The next state and next rule are written together after the current event's operation has been recorded.

25 / FORMAL PROGRESSION

Source progression and equation concordance

The latest instructions are kept in the order of their roles within the supplied conversations. This concordance records how those instructions enter the new specification.

Source instruction	Formal placement	Source location
Retain the operators rather than the object or surrounding narrative.	Dual-point structure, clearance, support and named action.	[B], pp. 5–6
Formalize the entire context.	The inherited kernel encloses preparation, signature, fields, lookup and readout.	[B], pp. 8–10
Keep the literal paradigm.	Compression, rotational shearing and planar anchoring.	[B], pp. 12–15
Doubly pack the pinions.	Two Klein carriers, two field channels and the two-product operation.	[B], pp. 15–17
Retain this personal signature and its curved lemets.	Original image, krul, base, tensor and snip-profile record.	[S], pp. 2–4
Apply the personal signature to the preparation.	Symbolic key S_{key} in the source's field and tensor schemas.	[G], pp. 2–3
Place T on the independent 1D time axis.	T indexes the profile; the vertex and snip epoch form a joint event record.	[G], pp. 4–5

Lettered source-equation register

Equation key	Source expression	PDF page
B.1 / B.2	Shell-interface / Klein-field zero interface.	[B], 21 / 17
H.1 / H.2	Endpoint pinning / pair and dilution ratio.	[H], 30–31
H.3 / H.4	Hadamard coupling / μ -mulsion output.	[H], 7–8
H.5 / H.6	Half-life / signed pin-field schema.	[H], 1 / 32
H.7–H.9	Kinematic expression and two LUT schemas.	[H], 28–29, 33
H.10	Time-bearing final LUT output.	[H], 33–34
G.1–G.3	Independent axis, closure and signature key.	[G], 4–5, 2
G.4–G.6	Tensor progression and signature field.	[G], 3–5

The edition's new tuples, profile names and output layout organize these expressions. Its inverse-log and butterfly displays expand the corresponding source algebra. Each selected expression remains attached to its named profile in the integrated record.

Source record [B], [H], [G] and [S], locations shown above. Source schemas include formulations recorded in the supplied conversations; the instruction rows identify the author's progression within those records.
